Frequently Asked Questions (FAQ)

Q1: What are the key differences between feedback and feedforward control in bioprocesses?

A1: Feedback control uses measurements of the process output to adjust the control input. It's

reactive, correcting deviations after they occur. Feedforward control uses measurements of disturbances affecting the process to predict and compensate for their effects **before** they impact the output. Ideally, a combination of both strategies is used for optimal control.

Q2: How do I choose the right sensor for my bioprocess?

A2: Sensor selection depends on the specific parameter you need to measure (pH, temperature, dissolved oxygen, etc.), the accuracy required, the process environment (sterile, harsh conditions), and the cost. Consult the solution manual for guidance on sensor characteristics and selection criteria.

Q3: What are the limitations of using model predictive control (MPC)?

A3: MPC requires an accurate process model, which can be challenging to develop for complex bioprocesses. It can also be computationally intensive, requiring significant processing power. Furthermore, the accuracy of predictions depends heavily on the quality of the model and the data used to build it.

Q4: How can I improve the robustness of my bioprocess control system?

A4: Robustness can be improved through: (1) Designing a control system with sufficient gain margin and phase margin, (2) Using robust control algorithms less sensitive to model uncertainties, (3) Implementing redundancy and fault detection mechanisms, (4) Careful sensor selection and calibration, and (5) Regularly validating the control system's performance.

Q5: What are some common challenges encountered in bioprocess control?
